Questions to cover today

- Q8
- Q9
- Q15
- Q16
- Q18
- Q19
- Q21

Q8. Sketch the short-run TC, VC, FC, ATC, AVC, AFC, and MC curves for the production function

$$Q = 3KL$$

K is fixed at 2 units in the short run, with r = 3 and w = 2.

• Short Run:
$$Q = 6L \implies L = \frac{Q}{6}$$

•
$$TC = rK + wL$$
 $\Rightarrow TC = 6 + 2\frac{Q}{6}$ $VC = 2\frac{Q}{6}$

•
$$ATC = \frac{TC}{Q}$$
 \Rightarrow $ATC = \frac{6}{Q} + \frac{1}{3}$

•
$$MC = \frac{dTC}{dO}$$
 \Rightarrow $MC = \frac{1}{3}$

etc.

Q9. When the average product of labour is the same as the marginal product of labour, how will marginal cost compare with average variable cost?

$$VC = wL$$

$$AVC = \frac{wL}{Q} = \frac{w}{AP}$$

$$MC = \frac{dVC}{dQ} = w\frac{dL}{dQ} = \frac{w}{MP}$$

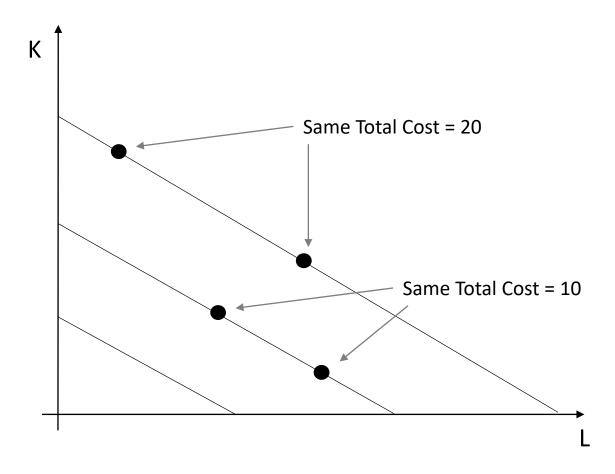

If
$$MP = AP$$
,
then $MC = AVC$

Q15. A firm purchases capital and labour in competitive markets at prices of r=6 and w=4, respectively. With the firm's current input mix, the marginal product of capital is 12 and the marginal product of labour is 18. Is this firm minimizing its costs? If so, explain how you know. If not, explain what the firm ought to do.

- r=6 and w=4
- MPK=12 and MPL=18
- Is the firm minimizing costs?

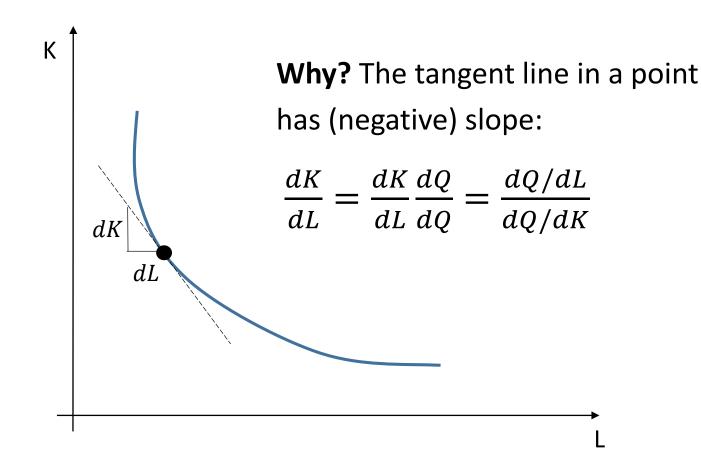

Isocosts

The slope of an Isocost line is $-\frac{w}{r}$

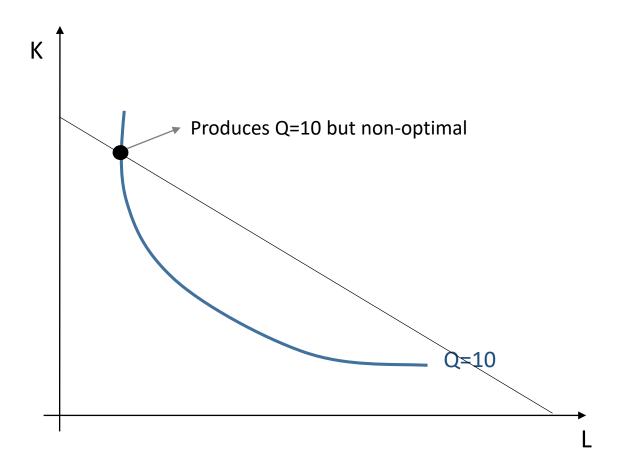

Isoquant

The slope of the isoquant in a point is $-\frac{MPL}{MPK}$

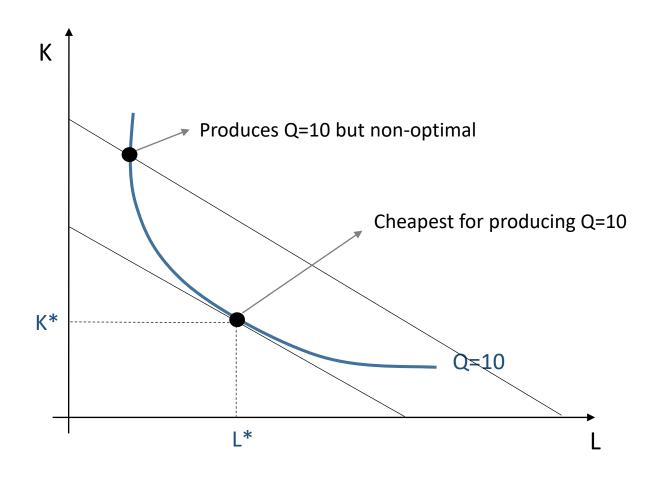

Cost Minimization Problem

For given Q and input prices, find cheapest combination of K and L

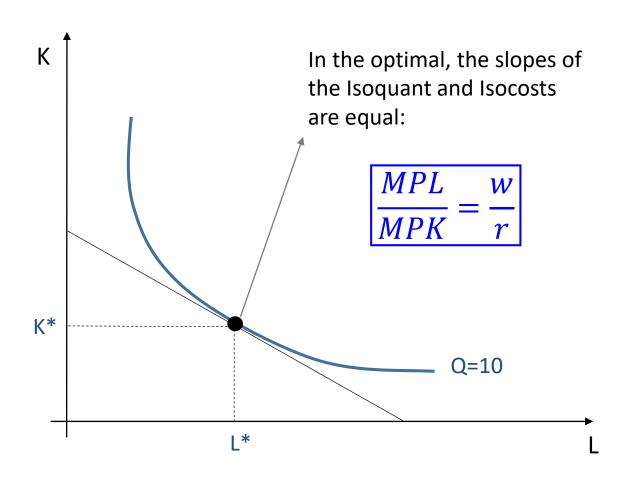

Cost Minimization Problem

For given Q and input prices, find cheapest combination of K and L

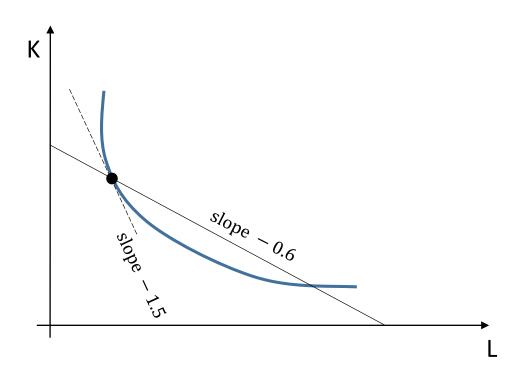

Cost Minimization Problem

For given Q and input prices, find cheapest combination of K and L

This Exercise

$$\frac{MPL}{MPK} = \frac{18}{12} = 1.5$$
 and $\frac{w}{r} = \frac{4}{6} = 0.6 \implies \text{Non Optimal}$

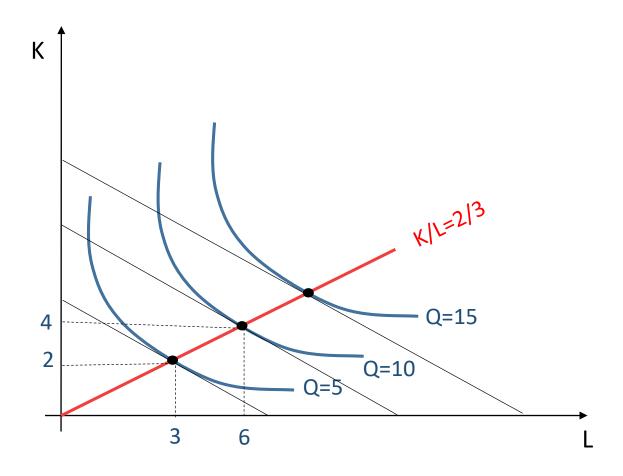

Q16. A firm has a production function Q = F(K, L) with constant returns to scale. Input prices are r = 2 and w = 1. The output-expansion path for this production function at these input prices is a straight line through the origin. When it produces 5 units of output, it uses 2 units of K and 3 units of L. How much K and L will it use when its long-run total cost is equal to 70?

- Production function has CRS
- r=2 and w=1
- Expansion path is a line trough the origin
- For Q = 5 we have K = 2 and L=3
- Question: Find K and L if TC = 70

Expansion Path

Optimal K/L as you increase production (at given prices)

Extra: How would this graph look with IRS or DRS?

Total Cost when Q = 5

$$\begin{array}{c}
rK + wL \\
2 \times 2 + 1 \times 3 = 7
\end{array}$$

CRS

Suppose we multiply <u>all</u> inputs by g>1. Then:

- Production increases by g
- Cost increases by $g: 2 \times 2g + 1 \times 3g = 7g$
- K/L is still 2/3

New situation with TC = 70

Because the expansion path is linear <u>we know</u> that K and L must have increased by the same proportion g so K/L is remained constant

Then, the new cost 70 can be written as:

$$2 \times 2g + 1 \times 3g = 70$$

$$\Rightarrow g = 10$$

Which means that K = 20 and L = 30

Q18. Sketch LTC, LAC and LMC curves for the production function Q=K+L.

Does this production function have constant, increasing or decreasing returns to scale?

- Perfect Substitutes (one-to-one substitution)
- Use only cheapest input

In either case, TC is linear, AC and MC are constant

The function has CRS:

$$Q(tK, tL) = tK + tL = t(K + L) = tQ(K, L)$$

Q19. A firm produces output with the production function

$$Q = \sqrt{KL}$$

If the price of labour is 1 and the price of capital is 4, what quantities of capital and labour should it employ if its goal is to produce 200 units of output?

- w=1 and r=4
- Want to produce Q=200
- Question: Find L and K

Use optimal condition $\frac{MPL}{MPK} = \frac{W}{r}$

$$\frac{\sqrt{K}/2\sqrt{L}}{\sqrt{L}/2\sqrt{K}} = \frac{K}{L} = \frac{1}{4}$$

$$\boxed{L = 4K} \tag{1}$$

Replace (1) into the production function

$$Q = \sqrt{K4K} = 2K$$

$$K = \frac{Q}{2} = 100$$
 and from (1) $L = 400$

Extra: Find the Long Run TC function

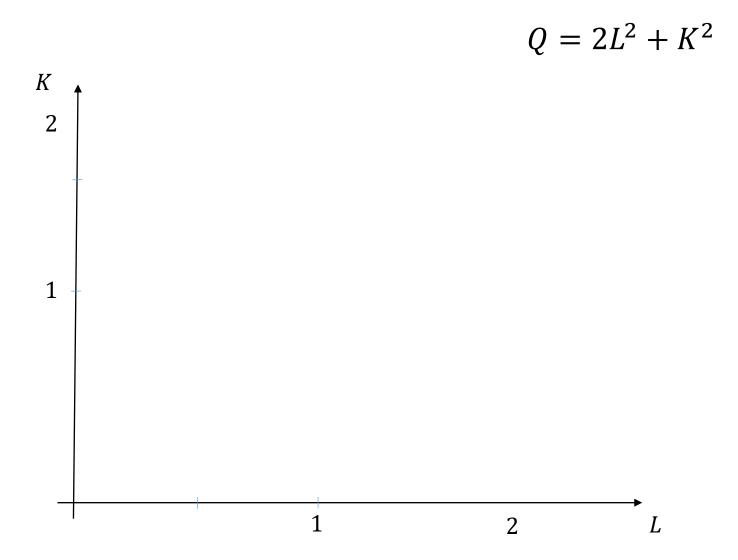

Q21. Suppose that a firm has production function:

$$Q(K,L) = 2L^2 + K^2$$

a) If the price of labour is 6 and the price of capital is 5 what is the long-run average cost and marginal cost curve?

- w=6 and r=5
- Find TC and MC long run

Key: Isoquants are concave!

Key: Isoquants are concave!

For
$$\frac{w}{r} = \frac{6}{5}$$
 \Rightarrow Use only L

$$Q = 2L^2 \quad \Rightarrow \quad \left| L = \left(\frac{Q}{2} \right)^{0.5} \right|$$

Replace into the definition of TC = wL + rK = 6L

$$TC = 6\left(\frac{Q}{2}\right)^{0.5}$$

b) Derive the short-run average total cost and marginal cost curve if K=4.

$$Q = 2L^2 + 16 \qquad \Rightarrow \qquad \left| L = \left(\frac{Q - 16}{2} \right)^{0.5} \right|$$

Then, use definition of TC = wL + rK = 6L + 20

$$TC^{SR} = 6\left(\frac{Q - 16}{2}\right)^{0.5} + 20$$
